The remainder of the slides in this presentation were created by Magee and Kramer for Chapter 8 of the Concurrency textbook

Model-Based Design

Design

Concepts: design process:

requirements to models to implementations

Models: check properties of interest:

- safety on the appropriate (sub)system
- progress on the overall system

Practice:model interpretation - to infer actual system behavior

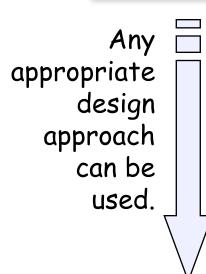

threads and monitors

Aim: rigorous design process.

8.1 from requirements to models

Requirements

- goals of the system
- scenarios (Use Case models)
- properties of interest

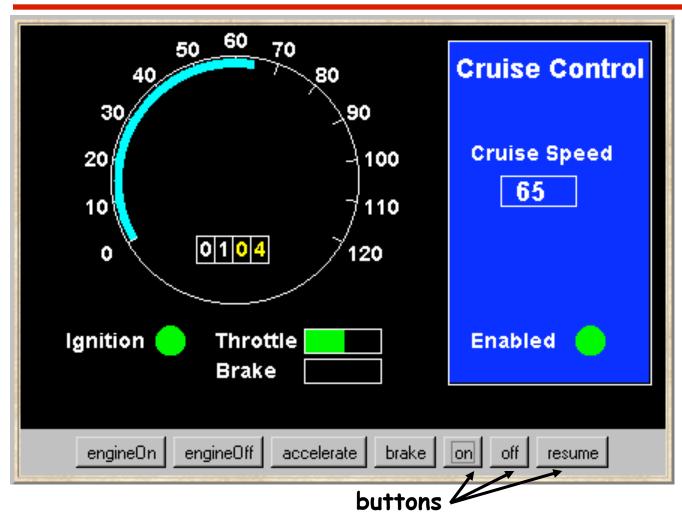

- identify the main events, actions, and interactions
- identify and define the main processes
- identify and define the properties of interest
- structure the processes into an architecture

Model

- check traces of interest
- check properties of interest

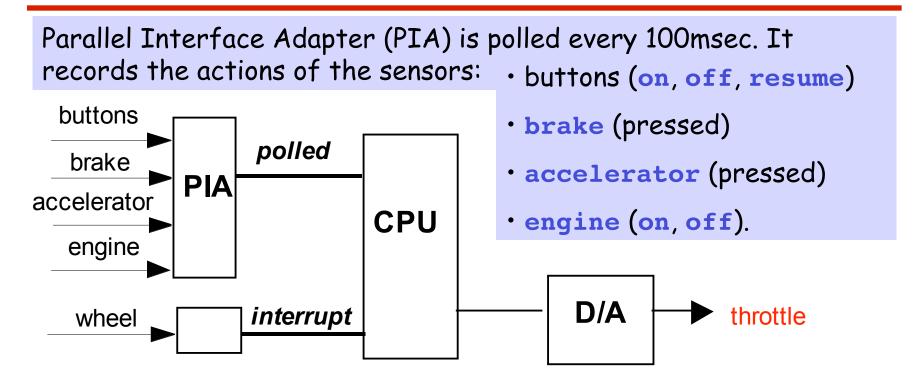

a Cruise Control System - requirements

When the car ignition is switched on and the on button is pressed, the current speed is recorded and the system is enabled: it maintains the speed of the car at the recorded setting.

Pressing the brake, accelerator or **off** button disables the system. Pressing **resume** or **on** reenables the system.

a Cruise Control System - hardware

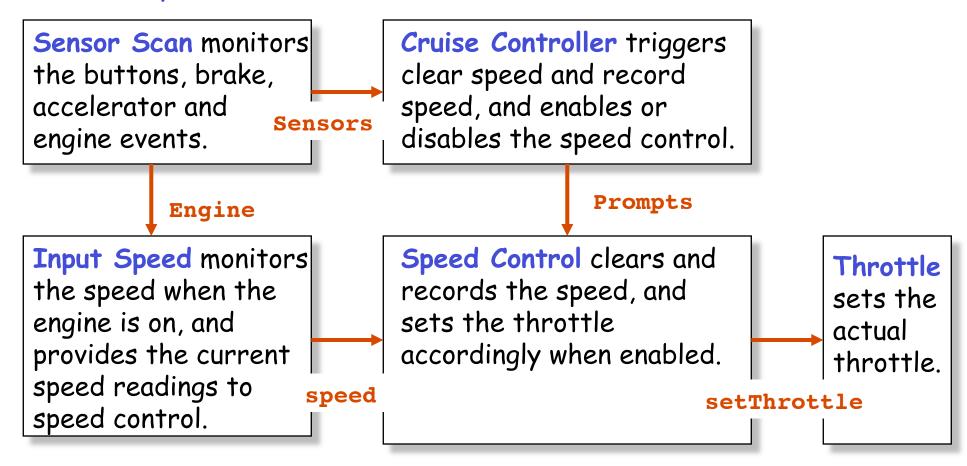

Wheel revolution sensor generates interrupts to enable the car speed to be calculated.

Output: The cruise control system controls the car speed by setting the throttle via the digital-to-analogue converter.

model - outline design

♦outline processes and interactions.

model -design

Main events, actions and interactions.

```
on, off, resume, brake, accelerator
engine on, engine off,
speed, setThrottle
clearSpeed, recordSpeed,
enableControl, disableControl

Sensors

Prompts
```

Identify main processes.

```
Sensor Scan, Input Speed,
Cruise Controller, Speed Control and
Throttle
```

Identify main properties.

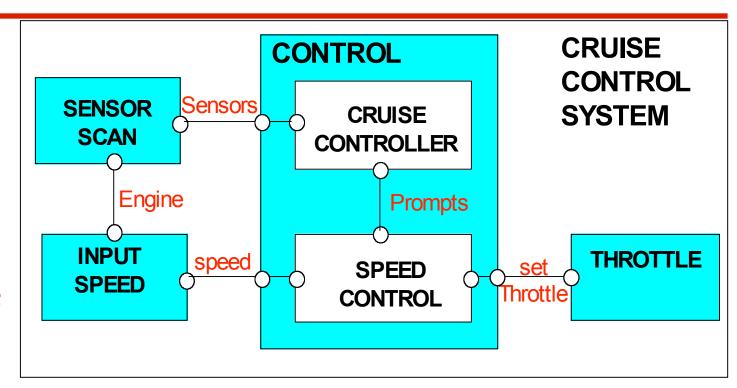

safety - disabled when off, brake or accelerator pressed.

Define and structure each process.

model - structure, actions and interactions

The CONTROL system is structured as two processes.

The main actions and interactions are as shown.

Concurrency: model-based design

model elaboration - process definitions

```
SENSORSCAN = ({Sensors} -> SENSORSCAN).
    // monitor speed when engine on
INPUTSPEED = (engineOn -> CHECKSPEED),
CHECKSPEED = (speed -> CHECKSPEED
              engineOff -> INPUTSPEED
     // zoom when throttle set
THROTTLE = (setThrottle -> zoom -> THROTTLE).
     // perform speed control when enabled
SPEEDCONTROL = DISABLED,
DISABLED =({speed,clearSpeed,recordSpeed}->DISABLED
            enableControl -> ENABLED
ENABLED = ( speed -> setThrottle -> ENABLED
           {recordSpeed,enableControl} -> ENABLED
            disableControl -> DISABLED
```

model elaboration - process definitions

```
set DisableActions = {off,brake,accelerator}
     // enable speed control when cruising, disable when a disable action occurs
CRUISECONTROLLER = INACTIVE,
INACTIVE =(engineOn -> clearSpeed -> ACTIVE
           DisableActions -> INACTIVE ),
         =(engineOff -> INACTIVE
ACTIVE
           on->recordSpeed->enableControl->CRUISING
           DisableActions -> ACTIVE ),
CRUISING = (engineOff -> INACTIVE
           DisableActions->disableControl->STANDBY
           on->recordSpeed->enableControl->CRUISING ),
         =(engineOff -> INACTIVE
STANDBY
           resume -> enableControl -> CRUISING
           on->recordSpeed->enableControl->CRUISING
           DisableActions -> STANDBY
```

model - CONTROL subsystem

Animate to check particular

traces:

- Is control enabled after the engine is switched on and the on button is pressed?
- Is control disabled when the brake is then pressed?
- Is control re-enabled when resume is then pressed?

However, we need analysis to check exhaustively:

- Safety: Is the control disabled when off,
 brake or accelerator is pressed?
- Progress: Can every action eventually be selected?

Safety checks are compositional. If there is no violation at a subsystem level, then there cannot be a violation when the subsystem is composed with other subsystems.

This is because, if the **Error** state of a particular safety property is unreachable in the LTS of the subsystem, it remains unreachable in any subsequent parallel composition which includes the subsystem. Hence...

Safety properties should be composed with the appropriate system or subsystem to which the property refers. In order that the property can check the actions in its alphabet, these actions must not be hidden in the system.

```
property CRUISESAFETY =
  ({DisableActions, disableControl} -> CRUISESAFETY
  | {on,resume} -> SAFETYCHECK
SAFETYCHECK =
  ({on,resume} -> SAFETYCHECK
  DisableActions -> SAFETYACTION
   disableControl -> CRUISESAFETY
SAFETYACTION = (disableControl->CRUISESAFETY).
                                                  LTS?
 | | CONTROL = (CRUISECONTROLLER
              SPEEDCONTROL
              CRUISESAFETY
                       Is CRUISESAFETY violated?
```

Safety analysis using LTSA produces the following violation:

Trace to property violation in CRUISESAFETY:

engineOn

clearSpeed

on

recordSpeed

enableControl

engineOff

off

off

Strange circumstances!

If the system is enabled by switching the engine on and pressing the on button, and then the engine is switched off, it appears that the control system is not disabled.

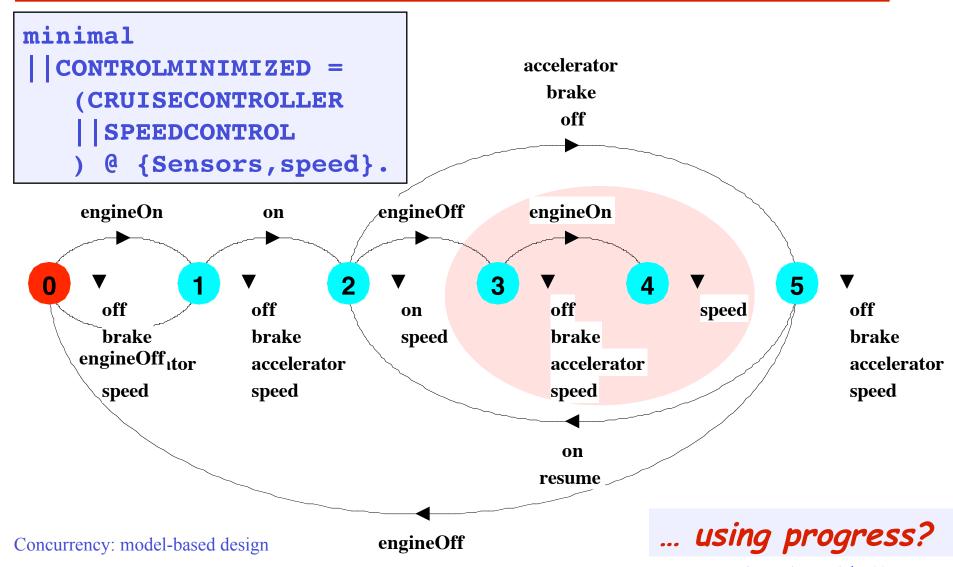

What if the engine is switched on again? We can investigate further using animation ...

engineOn
clearSpeed
on
recordSpeed
enableControl
engineOff
engineOn
speed
setThrottle
speed
setThrottle

The car will accelerate and zoom off when the engine is switched on again!

... using LTS? Action hiding and minimization can help to reduce the size of an LTS diagram and make it easier to interpret ...

Model LTS for CONTROLMINIMIZED

model - Progress properties

```
Progress violation for actions:
{accelerator, brake, clearSpeed, disableControl,
enableControl, engineOff, engineOn, off, on,
recordSpeed, resume}
Trace to terminal set of states:
     engineOn
     clearSpeed
     on
     recordSpeed
     enableControl
     engineOff
     engineOn
Cycle in terminal set:
     speed
     setThrottle
Actions in terminal set:
     {setThrottle, speed}
```

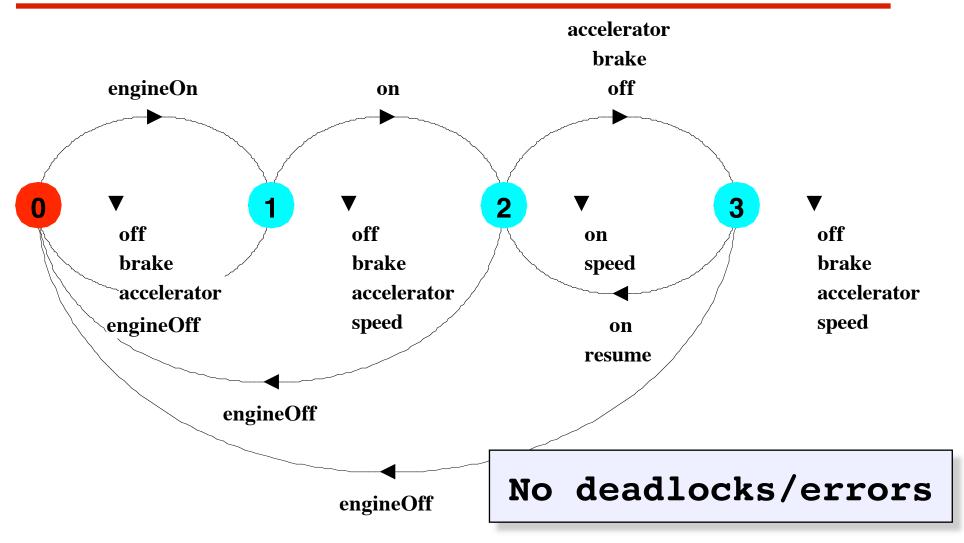

Check the model for progress properties with no safety property and no hidden actions

model - revised cruise controller

Modify **CRUISECONTROLLER** so that control is disabled when the engine is switched off:

Modify the safety property:

revised CONTROLMINIMIZED

model analysis

We can now proceed to compose the whole system:

```
||CONTROL =
    (CRUISECONTROLLER||SPEEDCONTROL||CRUISESAFETY
    )@ {Sensors, speed, setThrottle}.

||CRUISECONTROLSYSTEM =
    (CONTROL||SENSORSCAN||INPUTSPEED||THROTTLE).
```

Deadlock? Safety?

No deadlocks/errors

Progress?

model - Progress properties

Progress checks are not compositional. Even if there is no violation at a subsystem level, there may still be a violation when the subsystem is composed with other subsystems.

This is because an action in the subsystem may satisfy progress yet be unreachable when the subsystem is composed with other subsystems which constrain its behavior. Hence...

Progress checks should be conducted on the complete target system after satisfactory completion of the safety checks.

Progress?

Concurrency: model-based design

No progress violations detected.

model - system sensitivities

What about progress under adverse conditions? Check for system sensitivities.

```
|SPEEDHIGH = CRUISECONTROLSYSTEM << {speed}.
```

```
Progress violation for actions:
{engineOn, engineOff, on, off, brake, accelerator,
resume, setThrottle, zoom}
Path to terminal set of states:
     engineOn
     tau
Actions in terminal set:
{speed}
```

The system may be sensitive to the priority of the action speed.

model interpretation

Models can be used to indicate system sensitivities.

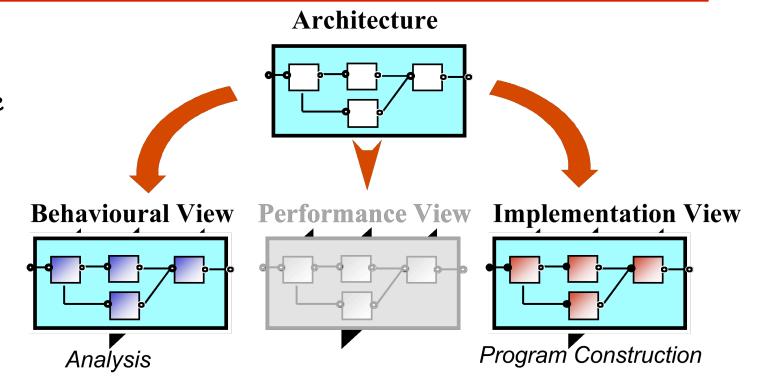

If it is possible that erroneous situations detected in the model may occur in the implemented system, then the model should be revised to find a design which ensures that those violations are avoided.

However, if it is considered that the real system will not exhibit this behavior, then no further model revisions are necessary.

Model interpretation and correspondence to the implementation are important in determining the relevance and adequacy of the model design and its analysis.

The central role of design architecture

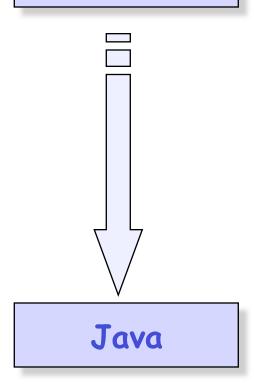

Design architecture describes the gross organization and global structure of the system in terms of its constituent components.

We consider that the models for analysis and the implementation should be considered as elaborated views of this basic design structure.

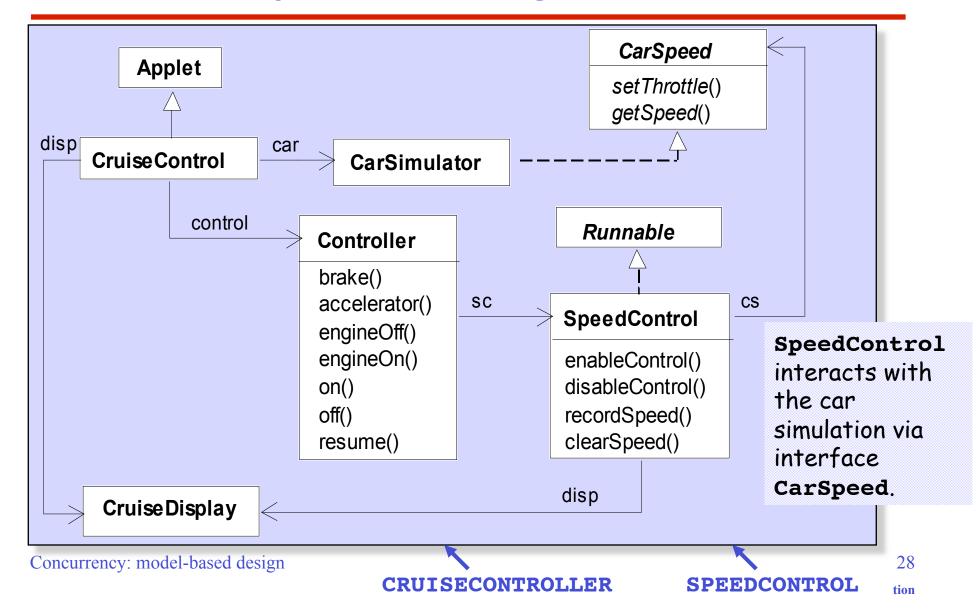

8.2 from models to implementations

Model

- identify the main active entities
 - to be implemented as threads
- identify the main (shared) passive entities
 - to be implemented as monitors
- identify the interactive display environment
 - to be implemented as associated classes
- structure the classes as a class diagram

cruise control system - class diagram

cruise control system - class Controller

```
class Controller {
  final static int INACTIVE = 0; // cruise controller states
                                                      Controller
  final static int ACTIVE
                             = 1;
                                                      is a passive
  final static int CRUISING = 2;
                                                      entity - it
  final static int STANDBY = 3;
  private int controlState = INACTIVE; //initial state
                                                      reacts to
  private SpeedControl sc;
                                                      events.
  Controller(CarSpeed cs, CruiseDisplay disp)
                                                      Hence we
    {sc=new SpeedControl(cs,disp);}
                                                      implement it
  synchronized void brake(){
                                                      as a monitor
    if (controlState==CRUISING )
      {sc.disableControl(); controlState=STANDBY; }
  synchronized void accelerator(){
    if (controlState==CRUISING )
      {sc.disableControl(); controlState=STANDBY; }
 synchronized void engineOff(){
    if(controlState!=INACTIVE) {
      if (controlState==CRUISING) sc.disableControl();
      controlState=INACTIVE;
```

cruise control system - class Controller

```
synchronized void engineOn(){
    if(controlState==INACTIVE)
      {sc.clearSpeed(); controlState=ACTIVE;}
                                                       This is a
                                                       direct
  synchronized void on(){
                                                       translation
    if(controlState!=INACTIVE) {
                                                      from the
      sc.recordSpeed(); sc.enableControl();
                                                       model.
      controlState=CRUISING;
  synchronized void off(){
    if(controlState==CRUISING)
      {sc.disableControl(); controlState=STANDBY;}
  synchronized void resume(){
    if(controlState==STANDBY)
     {sc.enableControl(); controlState=CRUISING;}
```

cruise control system - class SpeedControl

```
class SpeedControl implements Runnable {
                                                     SpeedControl
  final static int DISABLED = 0; //speed control states
  final static int ENABLED
                                                     is an active
 private int state = DISABLED; //initial state
                                                     entity - when
 private int setSpeed = 0;
                                 //target speed
                                                     enabled, a new
 private Thread speedController;
 private CarSpeed cs;  //interface to control speed
                                                     thread is
 private CruiseDisplay disp;
                                                     created which
  SpeedControl(CarSpeed cs, CruiseDisplay disp){
                                                     periodically
    this.cs=cs; this.disp=disp;
    disp.disable(); disp.record(0);
                                                     obtains car
                                                     speed and sets
  synchronized void recordSpeed(){
                                                     the throttle.
    setSpeed=cs.getSpeed(); disp.record(setSpeed);
  synchronized void clearSpeed(){
    if (state==DISABLED) {setSpeed=0;disp.record(setSpeed);}
  synchronized void enableControl(){
    if (state==DISABLED)
      disp.enable(); speedController= new Thread(this);
      speedController.start(); state=ENABLED;
```

cruise control system - class SpeedControl

```
synchronized void disableControl(){
   if (state==ENABLED) {disp.disable(); state=DISABLED;}
public void run() {      // the speed controller thread
  try {
     while (state==ENABLED) {
     double error = (float)(setSpeed-cs.getSpeed())/6.0;
    double steady = (double)setSpeed/12.0;
    cs.setThrottle(steady+error);//simplified feed back control
    wait(500);
   } catch (InterruptedException e) {}
   speedController=null;
```

SpeedControl is an example of a class that combines both synchronized access methods (to update local variables) and a thread.

Summary

- ◆ Concepts
 - design process:
 from requirements to models to implementations
 - design architecture
- ◆ Models
 - check properties of interest
 safety: compose safety properties at appropriate (sub)system
 progress: apply progress check on the final target system model
- ◆ Practice
 - model interpretation to infer actual system behavior
 - threads and monitors

Aim: rigorous design process.
