

Lecture 26: Design Patterns (part 2)

Kenneth M. Anderson
Object-Oriented Analysis and Design
CSCI 6448 - Spring Semester, 2003

Last Lecture

- Design Patterns
 - Background and Core Concepts
 - Examples
 - Singleton, Factory Method, and Adapter

Goals of Lecture

- Cover Additional Design Patterns
 - State
 - Iterator
 - Flyweight
 - Decorator
 - Observer
 - Composite

State

- Intent
 - Allow an object to alter its behavior when its internal state changes
- Motivation
 - TCPConnection example
 - A TCPConnection class must respond to an open operation differently based on its current state: established, closed, listening, etc.

State, continued

- Applicability
 - Use State when
 - an object's behavior depends on its state
 - operations have large, multipart conditional statements that depend on the object's state
- Participants
 - Context
 - defines the interface of interest to clients
 - maintains an instance of a ConcreteState subclass
 - State
 - defines an interface for encapsulating the behavior associated with a particular state of the Context
 - ConcreteState
 - each subclass of State implements a different behavior that implements the correct behavior for a particular state

State, continued

- Structure
 - Page 306 of Design Patterns
- Collaborations
 - Context delegates state-specific requests to the current ConcreteState object
 - A context may pass itself as an argument to the State object handling the request
 - Context is the primary interface of clients
 - Either Context or ConcreteState subclasses can decide which state succeeds another and under what circumstances

State, continued

- Consequences
 - State localizes state-specific behavior and partitions behavior for different states
 - State makes state transitions explicit
 - State objects can be shared
- Example
 - We saw an example of the state pattern back in Lecture 20

Iterator

- Intent
 - Provide a way to access the elements of an aggregate object (e.g. a collection class) sequentially without exposing its underlying representation
- Also Known As
 - Cursor
- Motivation
 - A collection may have multiple ways of being "traversed"; Iterator lets you keep traversal operations out of the core collection interface

Iterator, continued

- Applicability
 - Use the Iterator pattern
 - to access an aggregate object's contents without exposing its internal representation
 - to support multiple traversals of aggregate objects
 - to provide a uniform interface for traversing different aggregate structures (that is, to support polymorphic iteration)
- Participants
 - Iterator
 - defines an interface for accessing and traversing elements
 - ConcreteIterator
 - implements Iterator interface and keeps track of current position within collection
 - Aggregate
 - defines an interface for creating an Iterator (factory method)
 - ConcreteAggregate
 - implements the factory method

Iterator, continued

- Structure
 - page 259 of Design Patterns
- Collaborations
 - A ConcreteIterator keeps track of the current object in the aggregate and can compute the next object in the traversal
- Consequences
 - The Iterator pattern supports multiple traversals for each collection (e.g. inorder, preorder, postorder for trees)
 - Iterators simplify Aggregate interface
 - More than one traversal can occur on a single collection at once; as long as the traversal is read-only

Iterator, continued

- Implementation
 - The Iterator interface in the Java Collection classes
 - java.util.Iterator (interface)
 - java.util.List (interface)
 - java.util.LinkedList (class)
 - java.util.ListIterator (interface)
 - implementing subclass is private within List class

Flyweight

- Intent
 - Use sharing to support large numbers of fine-grained objects efficiently
- Motivation
 - Imagine a text editor that creates one object per character in a document
 - For large documents, that is a lot of objects!
 - but for simple text documents, there are only 26 letters, 10 digits, and a handful of punctuation marks being referenced by all of the individual character objects

Flyweight, continued

- Applicability
 - Use flyweight when all of the following are true
 - An application uses a large number of objects
 - Storage costs are high because of the sheer quantity of objects
 - Most object state can be made extrinsic
 - Many groups of objects may be replaced by relatively few shared objects once extrinsic state is removed
 - The application does not depend on object identity. Since flyweight objects may be shared, identity tests will return true for conceptually distinct objects

Flyweight, continued

- Participants
 - Flyweight
 - declares an interface through which flyweights can receive and act on extrinsic state
 - ConcreteFlyweight
 - implements Flyweight interface and adds storage for intrinsic state
 - UnsharedConcreteFlyweight
 - not all flyweights need to be shared; unshared flyweights typically have children which are flyweights
 - FlyweightFactory
 - creates and manages flyweight objects
 - Client
 - maintains extrinsic state and stores references to flyweights

Flyweight, continued

- Collaborations
 - Data that a flyweight needs to process must be classified as intrinsic or extrinsic
 - Intrinsic is stored with client; Extrinsic is stored with client
 - Clients should not instantiate ConcreteFlyweights directly
- Consequences
 - Storage savings is a tradeoff between total reduction in number of objects verses the amount of intrinsic state per flyweight and whether or not extrinsic state is computed or stored
 - greatest savings occur when extrinsic state is computed

Flyweight, continued

- See code example (available from class website)
- Simple implementation of flyweight pattern
 - Focus is on factory and flyweight rather than on client
 - Demonstrates how to do simple sharing of characters

Decorator

- Intent
 - Attach additional responsibilities to an object dynamically. Decorators provide a flexible alternative to subclassing for extending functionality
- Also Known As
 - Wrapper
- Motivation
 - Sometimes we want to add responsibilities to individual objects, not to an entire class (like adding scrollbars to windows in GUI toolkits)

Decorator, continued

- Applicability
 - Use Decorator
 - to add responsibilities to individual objects dynamically
 - for responsibilities that can be withdrawn
 - when extension by subclassing is impractical
- Participants
 - Component
 - defines interface of objects to decorate
 - ConcreteComponent
 - defines an object to decorate
 - Decorator and ConcreteDecorator
 - Decorator maintains a reference to component and defines an interface that conforms to Component's interface; ConcreteDecorator adds responsibilities to the component

Decorator, continued

- Structure
 - Page 177 of Design Patterns
- Collaborations
 - Decorator forwards requests to its Component object. It may optionally perform additional operations before and after forwarding the request
- Consequences
 - More flexibility than static inheritance
 - Avoids feature-laden classes high up in the hierarchy
 - A decorator and its component are not identical
 - Lots of little objects

Observer

- Intent
 - Define a one-to-many dependency between objects so that when one object changes states, all its dependents are notified and updated automatically
- Also Known As
 - Dependants, Publish-Subscribe
- Motivation
 - Need a way to update dependant objects while avoiding tight coupling
 - User Interface Example

Observer, continued

- Applicability
 - Use Observer
 - when an abstraction has two aspects, one dependent on the other
 - when a change to one object requires changing others and you don't know in advance who needs to change
 - when an object should notify objects but should not make assumptions about which objects need to be notified
- Participants
 - Subject
 - provides interface to add and delete observers
 - Observer
 - defines an updating interface for dependants
 - ConcreteSubject
 - stores the state being observed
 - ConcreteObserver
 - stores state that must be consistent with observed state

21

Observer, continued

- Structure
 - page 294 of Design Patterns
- Collaborations
 - ConcreteSubject notifies observers whenever it changes its observed state
 - After receiving a notification, ConcreteObserver gets state from ConcreteSubject
 - see sequence diagram on page 295 of Design Patterns

22

Observer, continued

- Consequences
 - Abstract coupling between Subject and Observer
 - Subjects do not know the concrete subclasses of their observers
 - Support for broadcast communication
 - Subject does not know who is listening
 - Unexpected updates
 - Change in state may update an unintended object, one we didn't suspect was an observer, or should only be observing at well-defined times

Composite

- Intent
 - Compose objects into tree structures to represent part-whole hierarchies
 - Composite lets clients treat individual objects and compositions of objects uniformly
- Motivation
 - Image programs that allow graphic primitives to be grouped into collections of objects
 - Many operations are shared, such as move(), copy(), paste(), draw(), etc.

24

Composite, continued

- Applicability
 - Use Composite when
 - you want to represent part-whole hierarchies
 - you want clients to be able to ignore the difference between compositions of objects and individual objects
- Structure
 - page 164 of Design Patterns

Composite, continued

- Participants
 - Component
 - declares the shared interface
 - declares child management operations
 - empty methods for leaves
 - defines an interface to retrieve parent
 - Leaf
 - implements shared interface
 - Composite
 - stores children
 - implements shared interface by delegating to children
 - implements child management operations
 - Client
 - Manipulates objects using the Component interface

Composite, continued

- Collaborations
 - Client uses the Component interface to interact with all objects
 - If the recipient is a leaf, then the request is handled directly
 - If the recipient is a composite, then the request is delegated to its children

Composite, continued

- Consequences
 - Composite allows primitive objects and composite objects to be treated transparently
 - especially since the child management functions are defined in the Component interface
 - Composite simplifies code in the client
 - It makes it easy to add new types of "leaves"
 - nothing needs to change to add a new type of component (not even the client)
 - Disadvantage: Difficult to create composites that have only certain types of leaves; you need to subclass the Composite class and use run-time checks to make sure that only "legal" children are added to it
